Import Data using Transform Maps (Spreadsheet)

Customer Journey Map for the ServiceNow Administrator who imports employee data from a spreadsheet

Prepared by the project team (team size 5)

MB Monika B, Team Leader

SCENARIO

Importing employee data from a spreadsheet into ServiceNow using Import Sets and Transform Maps, then verifying the records

	1 Entice	2 Enter	3 Engage	4 Exit	5 Extend
	How does the administrator first become aware that employee data must be imported?	What does the administrator experience as they begin loading the data?	In the core moments of the import, what happens?	What does the administrator experience as the import finishes and is checked?	What happens after the import is complete?
1 Steps What does the administrator typically do at each point?	**Receive file** HR sends the employee data to the administrator as an Excel spreadsheet. **Check data** Admin checks the columns and looks for blank or duplicate Employee IDs. **Open Load Data** Admin opens Load Data in ServiceNow to start the import.	**Upload file** Admin chooses the Excel file and names the Import Set table. **Load to staging** The rows load into the Import Set table, which acts as a staging area. **Review rows** Admin checks that the loaded rows match the spreadsheet.	**Create map** Admin creates a Transform Map from the Import Set table to the Employee table. **Map fields** Employee ID, Name, Email, Department and Location are mapped. **Set coalesce** Admin sets Employee ID as the coalesce field to find existing records. **Run transform** Existing employees are updated and new ones are inserted.	**Check history** Admin opens the transform history to see inserted and updated counts. **Verify records** Admin compares the Employee table records with the spreadsheet. **Fix issues** Errors are corrected in the file or mapping and the import is re-run.	**Owner informed** The data owner is told that the employee data has been imported. **Reports built** Reports show employees by department and location. **Dashboard reviewed** Team reviews the Employee Analytics Dashboard.
2 Interactions What interactions do they have at each step along the way?	Email or shared drive with the Excel file from HR Excel spreadsheet on the administrator's computer System Import Sets > Load Data in the ServiceNow web UI	File chooser and Import Set table name field The file uploads in the browser. No code is needed. Import Set table created from the file Loaded rows appear in the Import Set Rows list Import Set Rows list and column headers	System Import Sets > Transform Maps > New Field Maps related list in the Transform Map Auto Map Matching Fields, then manual changes Coalesce checkbox on the Employee ID field map Transform button on the Import Set page	Transform History and Import Set state Employee table list view in the web UI Spreadsheet and the Transform Map field maps	Email or message to the data owner Reports created on the Employee table Employee Analytics Dashboard in ServiceNow
3 Goals & motivations At each step, what is the administrator's primary goal? ("Help me..." or "Help me avoid...")	Help me receive the data in a usable format Help me avoid importing bad data Help me start with the right import tool	Help me upload the file without errors Help me keep raw data in a safe staging area Help me confirm every row loaded	Help me send data to the right target table Help me map each column correctly Help me avoid duplicate employees Help me update and add records in one run	Help me see exactly what the import did Help me trust the data in the table Help me fix mistakes with little rework	Help me tell the owner the data is ready Help me turn the data into reports Help me improve the import next time
4 Positive moments What steps does a typical administrator find easy, helpful, productive or satisfying?	Load Data wizard is simple to start	No scripting needed, just upload the file Staging table keeps live data safe Rows can be reviewed before the transform	Auto Map Matching Fields saves time Employee ID coalesce prevents duplicates	Transform history shows clear counts Records can be compared quickly	Reports are built from accurate data Dashboard gives a quick overview
5 Negative moments What steps does a typical administrator find frustrating, confusing or time-consuming (before Import Sets and Transform Maps)?	Blank or duplicate IDs are easy to miss	A wrong file or table name causes errors Headers with extra spaces load incorrectly	A wrongly mapped field puts data in the wrong column Without coalesce, duplicates are created Mapping mistakes show only after the transform runs	Some rows may be skipped without notice Manual comparison with Excel is time-consuming	Wrong data gives wrong report numbers
6 Areas of opportunity How might we make each step better? Which Import Set or Transform Map setting helps?	How might we make the file easy to prepare before upload?	Use a clean Excel template with fixed column headers Check the Import Set table before running the transform Show row counts to confirm the load is complete	Use Auto Map Matching Fields, then review each mapping Set Employee ID as coalesce to update, not duplicate Run the transform on a small sample file first Transform script: skip rows with a blank Employee ID	Review inserted, updated and ignored counts Compare a few records with the spreadsheet Create reports for employees by department and location	Reuse the Transform Map for future spreadsheet imports

Journey stages: Entice, Enter, Engage, Exit, Extend. "Positive" and "Negative" moments describe the data import before and after Import Sets and Transform Maps are applied.
